Noatum Logistics

Customer Information Platform
Visual briefing for management

CUSTOMER INFORMATION PLATFORM

One portal where our customers see and do everything.

Track, quote, book, download, pay and get alerts — in one login, in the Noatum brand. The portal connects to the system our operations teams already use, so nothing is typed twice.

TODAY	WITH THE PORTAL
Customer emails or calls to ask where cargo is	Customer sees every shipment and milestone live
Quotes prepared by hand and sent as attachments	Instant price where rates exist, or a request routed to the branch
Documents and invoices requested one by one	Downloads documents and views invoices themselves
Several disconnected tools with separate logins	One login, one Noatum brand, in every country

What the portal does

Everything a customer needs from us, in one place.

Track

Shipments, containers, flights, live milestones

Quote

Instant price or branch-priced request

Book

From a quote or directly, with documents

Documents

Download singly or as a package

Invoices

See charges and credit notes

Alerts

Delays, customs holds, disruptions

Claims

Raise and follow incidents

Reports

Standard and self-service

Own users

Customer manages its own people

CO2 and insight

Emissions per shipment, predictive ETA

What it is not

Not an operations system

Our operations teams keep working in their existing system

Not a pricing system

The portal shows prices; it does not set them

Not a purchase-order tool

Visibility and deep links only

Not a brand redesign

The Noatum design system is used as it is

How the platform works

Five layers. The customer works on the top one. Shipment updates come in and quote requests go out only through the bottom one.

Customers and Noatum staff

Customer screens

Where the customer tracks, quotes and books

- Track a shipment
- Request a quote
- Make a booking
- Download documents
- View invoices
- Manage users

Business rules

Decides what each customer may see and do

- Which shipments belong to this customer
- Who may book or see invoices
- When a quote can still be accepted
- When to raise a delay alert

Shipment data

Kept in the portal so screens open instantly

- Shipments and milestones
- Containers, vessels, flights
- Quotes and bookings
- Documents and invoices
- Customers and users

Integration

The single connection to systems outside the portal, inside the same service

- Receives milestones, documents, invoices
- Sends quote requests and bookings
- Looks up rates
- Sends emails and PDFs
- Opens claims

Outside systems

Run by other teams

- Operations system (CargoWise One)
- Rate system
- Claims system (Dynamics 365)
- Shipping line and airline data

Screens never decide

Whether a customer may see a shipment or accept a quote is decided in the business-rules layer and checked again there, whatever the screen shows.

Fast because the data is already here

Shipment lists and timelines open instantly because the portal holds its own copy. New milestones from operations refresh that copy as they happen.

One connection point, many adapters

Each outside system has its own adapter in the integration layer, and they all run inside one service. A new carrier feed or a different operations system later means a new adapter, not a new portal.

Phase by phase — for your confirmation

We start with one pilot customer in one region and add features in the order below. Each phase is complete and usable on its own. Please confirm the phases you agree with and mark anything you want changed.

PHASE 1

Set-up and quotes

The customer can

- Log in with their own users and roles
- Request a quote for air, sea FCL or sea LCL
- Get an instant price where we have rates, otherwise a priced quote from our team
- Accept the quote and download it as a PDF

Behind it: customer set-up, data separation, connection to the operations system, Noatum brand.

Done when the pilot customer is quoting live

PHASE 2

Tracking

The customer can

- See every shipment, container and flight with live milestones
- Download documents
- View invoices and credit notes
- Receive alerts for delays and customs holds
- Run standard reports

Behind it: shipment data flowing in from the operations system; public track and trace page.

Done when the pilot customer tracks and downloads in the portal

PHASE 3

Booking and claims

The customer can

- Book from an accepted quote, or book directly
- Upload their shipping documents
- Pick a sailing
- Raise a claim and follow it
- Set their own email alert rules

Behind it: bookings created in the operations system; claims in Dynamics 365.

Done when a portal booking runs end to end

PHASE 4

Insight

The customer can

- See predicted arrival times
- See CO2 per shipment; use the public CO2 calculator
- Build their own reports; use Power BI dashboards
- Ask the AI assistant

Behind it: prediction models, emissions engine, analytics store. Every automated figure can be checked and corrected by a person.

Done when predictions and analytics are live for pilot customers

PHASE 5

Open up

The customer can

- See purchase orders against shipments
- Pull their data into their own systems
- Use the portal in more languages

Behind it: public API, data feeds, more regions and customers, a second operations system if ever needed.

Done when a customer consumes our data directly

Start small

Phase 1 is one customer, one region, one flow: quotes. Nothing else is switched on for them until it is ready.

Foundation first

Customer set-up, data separation and the connection to the operations system are built in Phase 1 and never rebuilt. Every later phase adds screens on top.

Switch on per customer

Every feature ships switched off and is turned on customer by customer. Adding the second customer or region is configuration, not a new project.

How we build each feature

Data	Shared contract	Logic	Screen
tables and rules	one definition for all	with tests	in Noatum brand

One feature at a time, in this order, finished and shown before it is handed over.

How a customer is onboarded

Nobody signs up on their own. Our team sets up the company; the company then sets up its own people.

1

NOATUM TEAM

Create the customer

Company name, country, and which features are switched on

2

NOATUM TEAM

Connect the customer's records

Choose which of our existing records belong to this company. Proposed: a second colleague confirms

3

NOATUM TEAM

Invite the customer's admin

A branded email with a secure link

4

CUSTOMER ADMIN

Accept and log in

With their company login or a secure account with two-step verification

5

CUSTOMER ADMIN

Invite colleagues

Assign roles: Standard, Quoting and Booking, Finance, Analyst, Claims, Admin

6

CUSTOMER USERS

Ready to work

Address book, saved templates, alert preferences. Their shipments are already there

After step 3 our team steps back. Adding and removing users belongs to the customer. Every action is recorded.

The CargoWise simulator

The portal needs to talk to our operations system, CargoWise One. Access to a test copy of it depends on another team. So we build a small stand-in first, develop and demo against it, and switch to the real system by changing a setting.

It does

- Accept our quote and booking messages and reply with prices and confirmations
- Push fake shipments, milestones, documents and invoices
- Hold a small test world of organisations, lanes and shared shipments

It is not

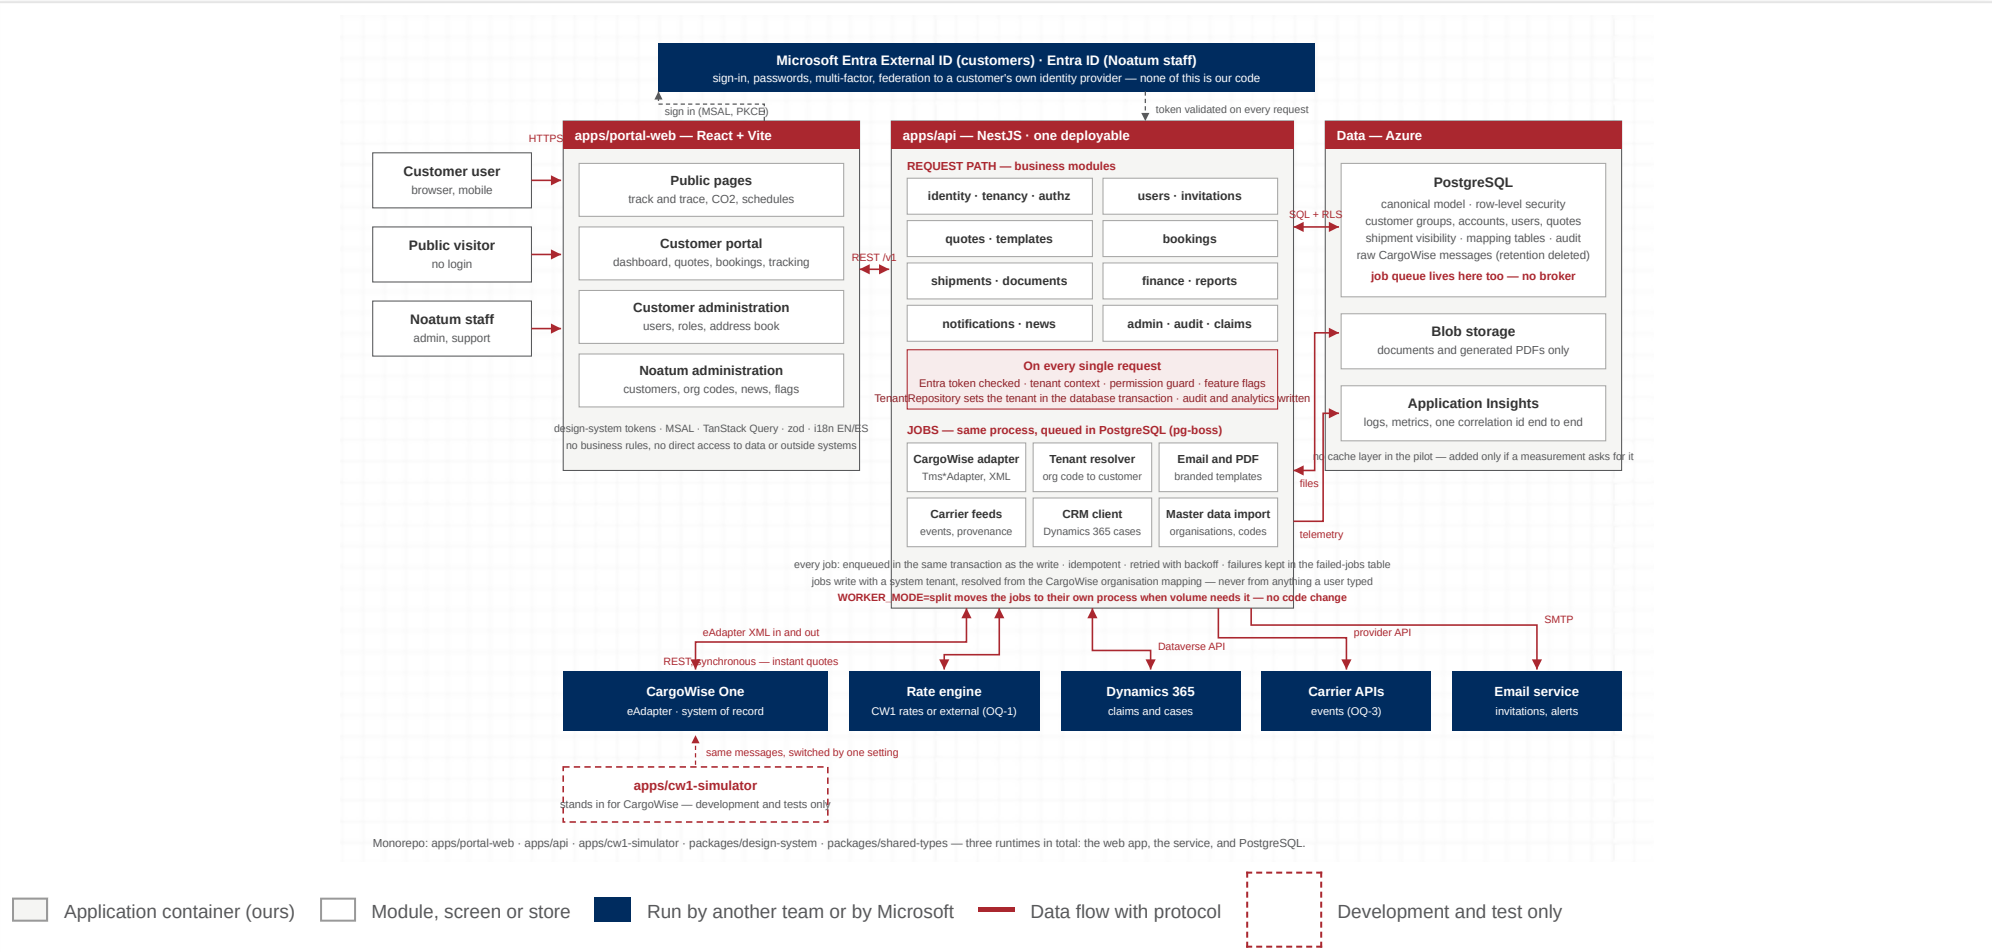

- A copy of the operations system — no business logic
- A second source of truth — switched off in production
- Final until real sample messages are confirmed

It gives us

- End-to-end demos before real access
- Realistic tests for customer data separation
- A permanent automated test environment

Application architecture

For the technical team. The portal is deliberately small: one web app, one service, one database. Microsoft Entra handles sign-in, so we write no login code. Background work runs as jobs inside the same service, queued in the same database, so there is no separate worker and no message broker to operate.

Deliberately small

One web app, one service, one database, plus file storage. No cache server, no message broker, no separate worker, and no login code of our own. Fewer moving parts means fewer things to operate and fewer places to fail.

Still flexible

Every outside system sits behind an adapter, jobs sit behind a queue interface, and the customer's login method is a setting. A cache, a broker, a separate worker or a second transport system can be added later without touching the data model.

Safety is not simplified

Customer separation is enforced twice: by the data-access layer and by the database itself. Every request carries a permission check. Every automated value carries where it came from and can be corrected by a person.

What we need from other teams

None of this is code, and none of it can be done by the development team alone. We can progress a long way on the simulator; after that these become blockers.

Now

CargoWise team

- Named contact
- Sample messages
- How customers are identified
- Organisation list
- Code lists
- Later: test instance with the door enabled

Next

IT and identity

- Entra External ID tenant
- App registrations per environment
- Email sending service
- Password and two-factor policy

Next

Azure and DevOps

- Subscription and environments
- Database, cache, queue, storage
- Key vault
- Test environment before the pilot

Now, one meeting

Business

- Customer tier definitions
- Confirm the six roles
- Who approves code links
- Email-domain rule
- Pilot customers

Before pilot

Brand and legal

- Logo files and brand font
- Email wording EN and ES
- Privacy notice and terms
- Retention periods

Requests to the CargoWise team

Written to be forwarded as is. The first seven items take about half a day and unblock a long stretch of work.

Customer Information Platform — information and access requests

From the platform development team · 04.09.2026

Purpose. We are building a customer portal that reads shipment, document and invoice data from CargoWise One and sends customer quote requests and bookings back into it. We need the items below to build against an accurate test stand-in first, and connect to a real test instance later.

A. Needed now — half a day

- ☐ **1. A named contact and a backup**
  Answers message-format questions within one working day.
- ☐ **2. Sample XML messages, anonymised**
  UniversalShipment (sea FCL and air), UniversalEvent, UniversalTransaction (invoice), eDoc, quote message if one exists.
- ☐ **3. Which element identifies each party on a shipment**
  Local client, shipper, consignee, notify party, agent — and which one is "the customer" for invoicing. This decides who may see a shipment.
- ☐ **4. Export of the organisation list**
  Code, name, country, branch, status, parent or related link. CSV to start; a scheduled feed later.
- ☐ **5. Event and milestone codes**
  Air and sea, with descriptions, marking internal-only codes.
- ☐ **6. Charge codes and document types**
  In use, with descriptions.
- ☐ **7. Status values**
  For quotes, bookings and shipments as CargoWise sends them.

B. Needed next — before the first real connection

- ☐ **8. Is eAdapter licensed and enabled**
  On which instances (TEST, UAT, PROD), and who administers it.
- ☐ **9. Message types enabled**
  Outbound: shipment, event, transaction, eDoc, quote. Inbound: quote request, booking.
- ☐ **10. How outbound messages are triggered**
  Pushed on save, scheduled, or polled; delivery method (HTTPS, SFTP, queue).
- ☐ **11. Authentication for both directions**
  Certificates, credentials, IP allow-listing.
- ☐ **12. A TEST instance with seeded data**
  We may send messages into it and see the result in CargoWise screens.
- ☐ **13. Where our portal reference can be stored**
  AdditionalReference, custom field or note, so replies can be matched.
- ☐ **14. Source of instant quote prices**
  CargoWise rate management or an external engine; if CargoWise, how rates are queried in real time.
- ☐ **15. Daily volumes**
  Shipments, events, documents, invoices per day and peak hours.

C. Needed before the pilot go-live

- ☐ **16. Pilot customers' organisation codes**
  All offices and the owning Noatum branch.
- ☐ **17. Historical data**
  One-time load of open shipments for pilot customers, or start from the connection date.
- ☐ **18. Change-control process**
  How we are told when fields, codes or triggers change.
- ☐ **19. Behaviour when our endpoint is unavailable**
  Retry, queue or drop.
- ☐ **20. Who signs off**
  That a portal-created quote or booking is acceptable to operations.
